LZ77

two passes over ST

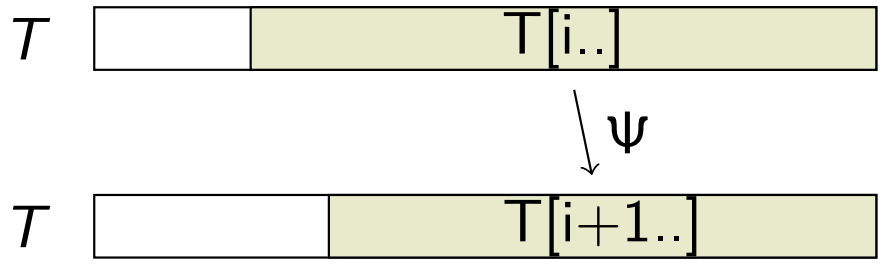
1. pass
   - traverse from *every* leaf to the root
   - mark visited nodes
   - already marked nodes $\equiv$ some reference
   - these nodes witness references
2. pass
   - same procedure
   - we know witnesses already!
   - which leaf discovers a witness first?

tricks & techniques

compressed suffix tree (CST)

lightweight ST

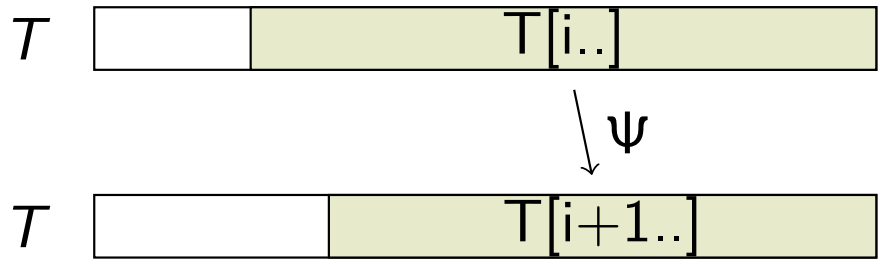
- Ψ array
- BP tree topology



compressed suffix tree (CST)

lightweight ST

- Ψ array
- BP tree topology



Theorem (Belazzougui'15)

can construct CST in

- *time*
  - $\mathcal{O}(n)$ *randomized or*
  - $\mathcal{O}(n \lg \lg \sigma)$ *deterministic*
- $\mathcal{O}(n \lg \sigma)$ *space*

traversal simulation

Problem

ad-hoc not efficient in CST

- *select leaf with given label*
- *read string from root to given node (string depth)*

leaf access

- leaf $`1' = \Psi[1]$
- nextleaf : (leaf $`k'$) $\mapsto$ (leaf $`k+1'$)
  - Ψ
  - $\text{rank}_{()}$ on BP
  - $\text{select}_{()}$ on BP

traversal simulation

Problem

ad-hoc not efficient in CST

- *select leaf with given label*
- *read string from root to given node (string depth)*

string depth

- *head*(ℓ) : first character on the path from root to leaf ℓ
  - make alphabet effective
  - answer: *child_rank* on highest ancestor $\neq$ root
- *str_depth*(v)
  - Ψ
  - head
  - time linear to string depth
  - used for factor length computation $\Rightarrow \mathcal{O}(n)$ time overall

summary

Theorem

given text T of length n, LZ77 of T can be computed with

- *time*
  - $\mathcal{O}(n)$ *randomized*
  - $\mathcal{O}(n \lg \lg \sigma)$ *deterministic*
- $\mathcal{O}(n \lg \sigma)$ *bits space*

same holds for LZ78! (see paper)

techniques:

- compressed suffix tree
- simulating suffix array with Ψ
- indirect matching (witnesses).

Thank you for listening. Any questions are welcome!
